

Supplementary Data 1

In this document, we present 60 evolved landscape samples for neuromesoderm differentiation (data from Sáez et al., 2022).

The layout of each page is as follows:

- A. Cellular trajectories in a simulation for experiment 5;
- B. Left: Basin escape numerical experiment with increased noise magnitude in the CHIR signalling regime. All cells were initialized in M state. Cellular trajectories and a potential contour plot are shown. Right: stream plot of the dynamics in the CHIR signalling regime. Crossings of nullclines indicate fixed points. Diamonds indicate locations of modules;
- C. Potential cross sections along green vertical lines in B;
- D. Potential surface between the first and last cross section;
- E. Comparison of simulated cell state proportions to fitted data over 7 experiments.

Landscapes were categorized based on the topology of the CE - PN/M decision, inferred from the locations of the saddles and the escape experiment. Two binary decision topologies are observed:

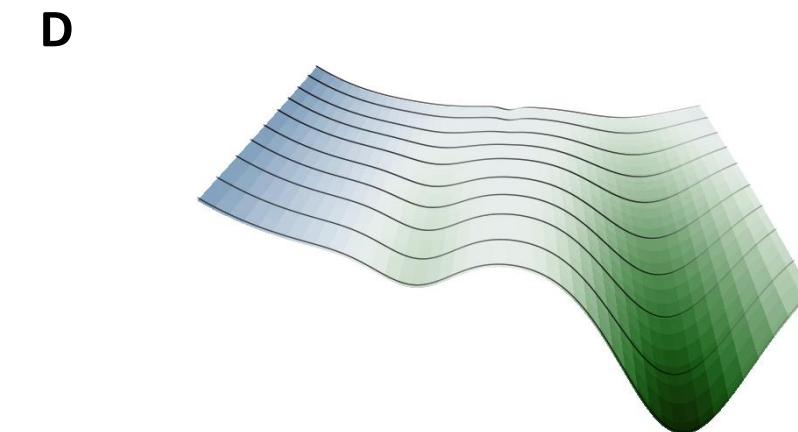

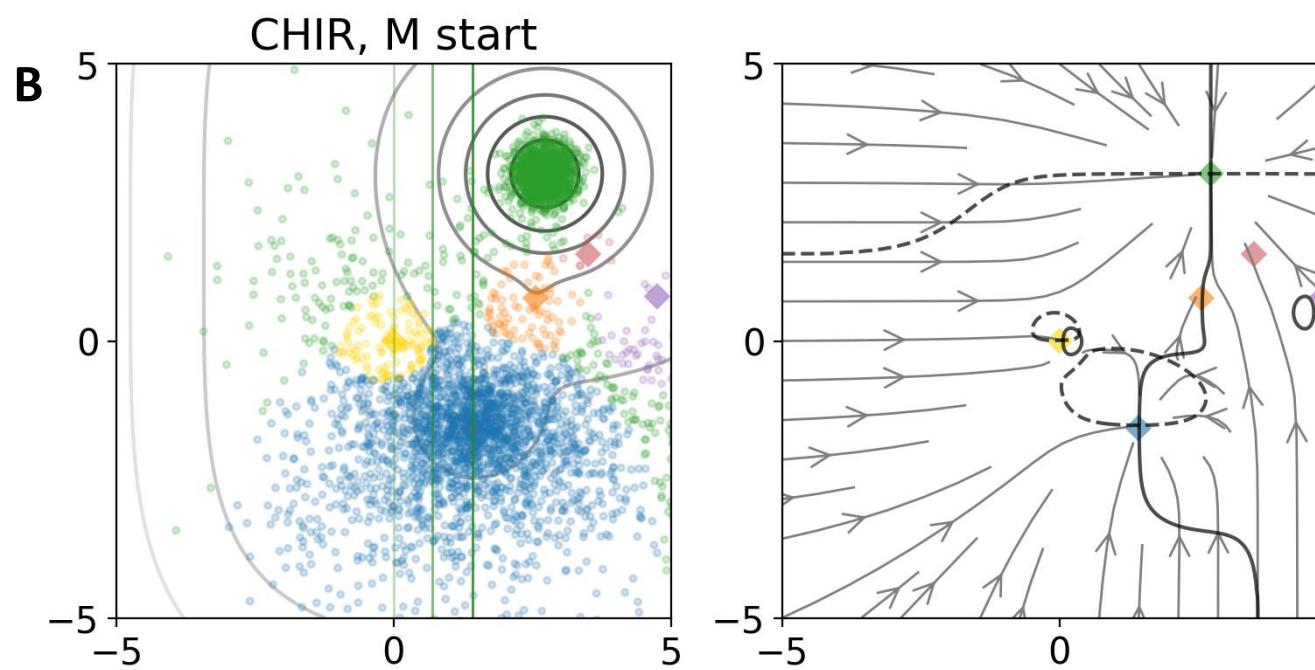

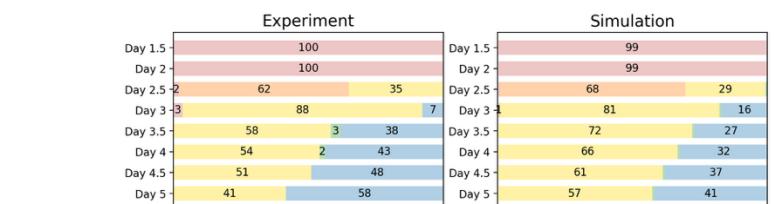

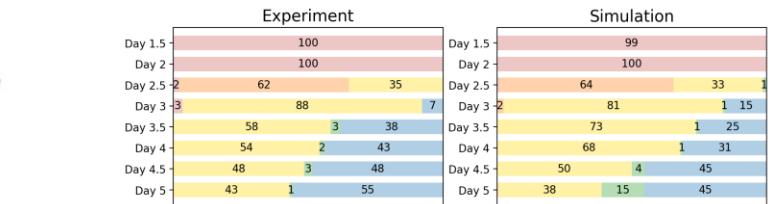

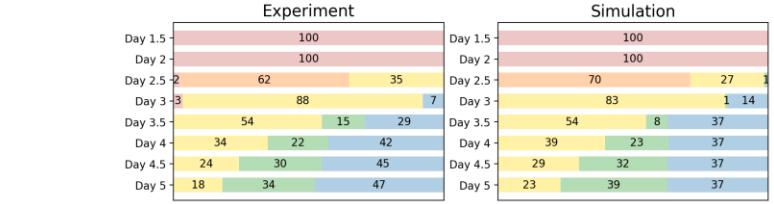

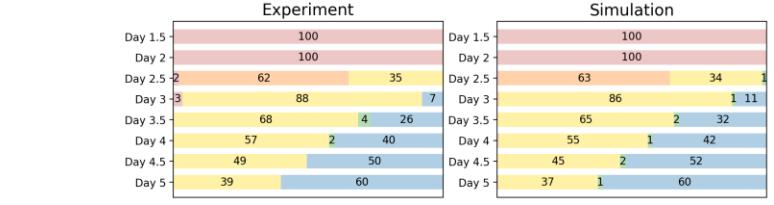

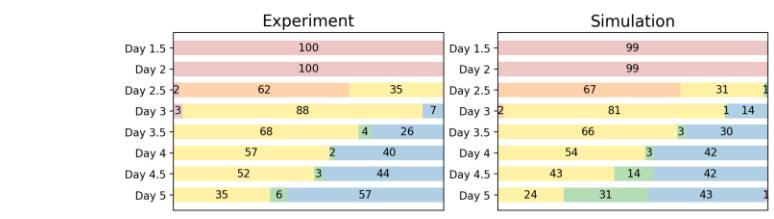

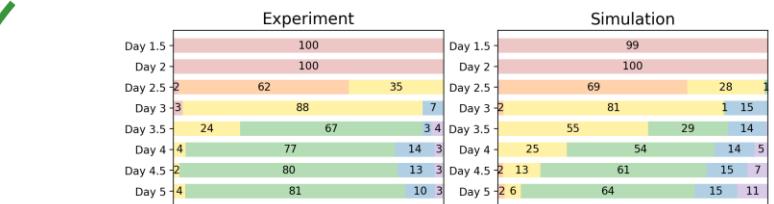

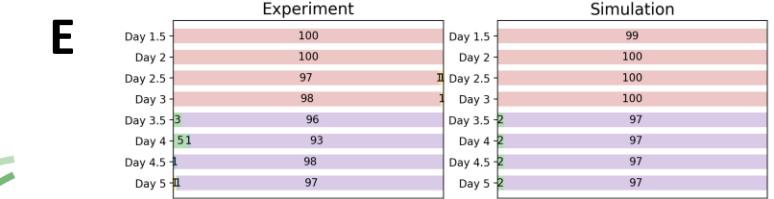

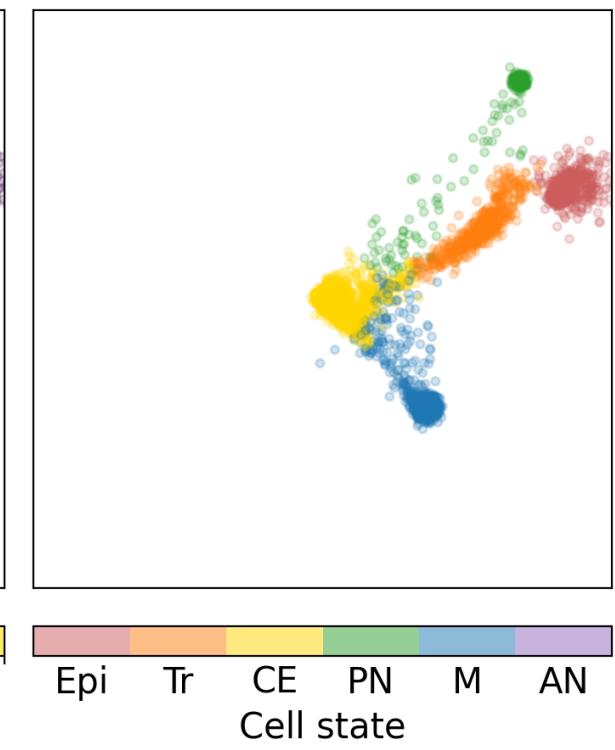

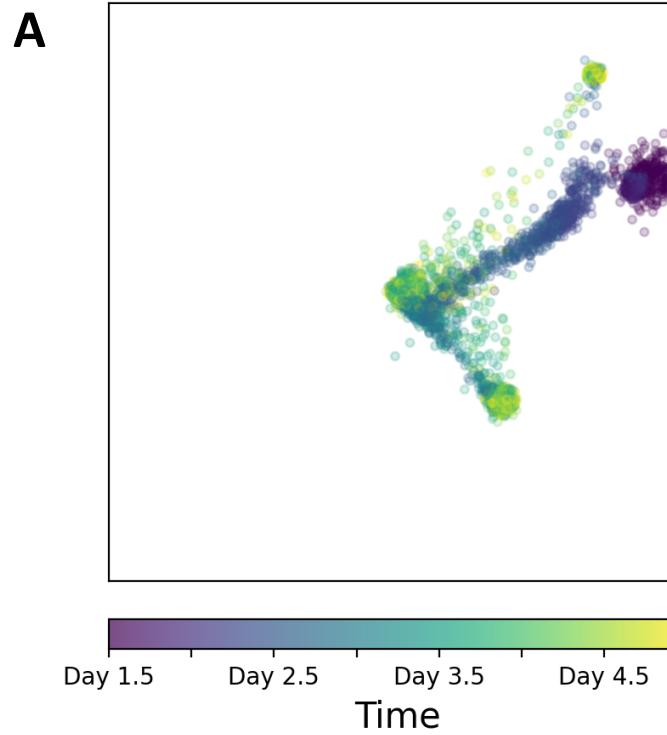

Heteroclinic flip: triangular topology with a saddle between PN and M. A subcategory *Heteroclinic flip with overlap* was separated based on significant spatial overlap of the flip landscape with the initial decision (Epi - Tr - CE)

Double cusp: linear topology, with no direct path from M to PN. A subcategory *Flat double cusp* was defined based on the shape of the potential.

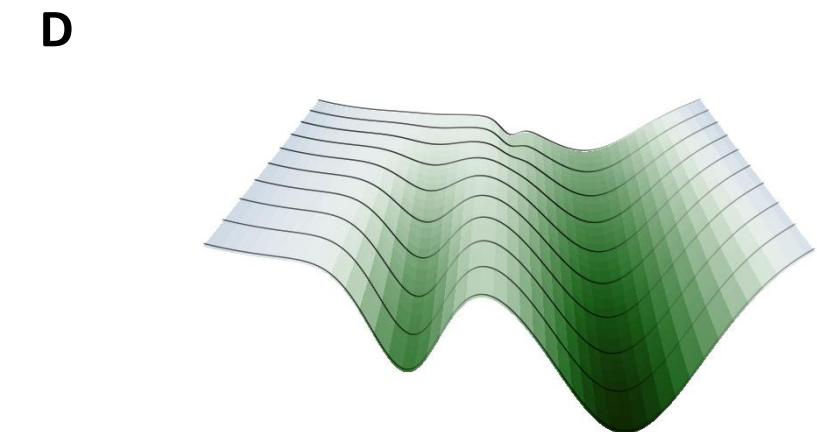

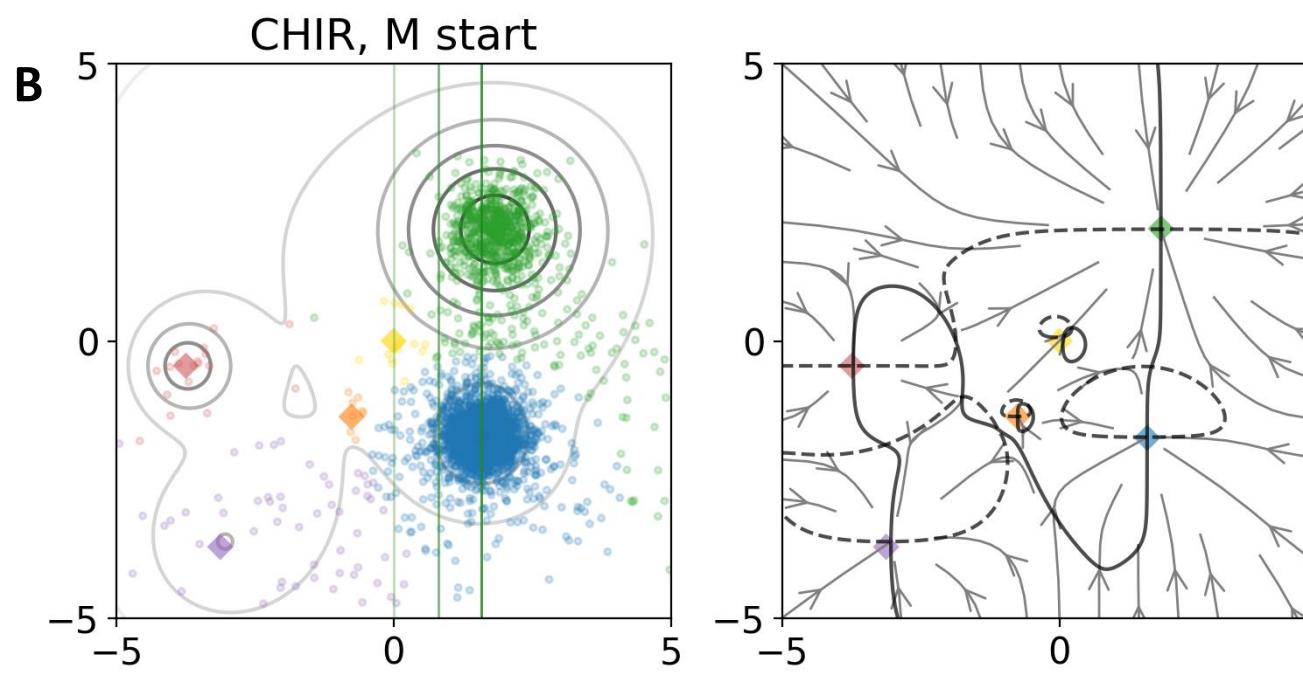

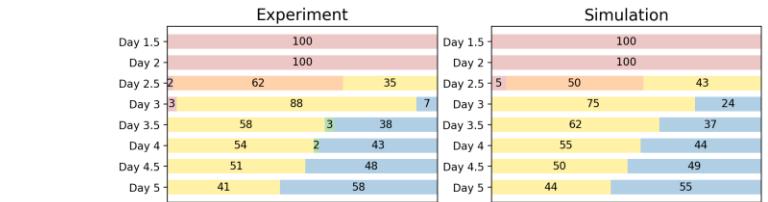

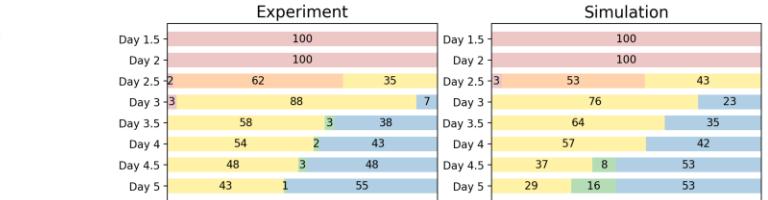

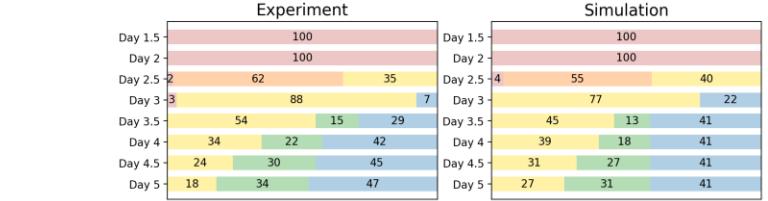

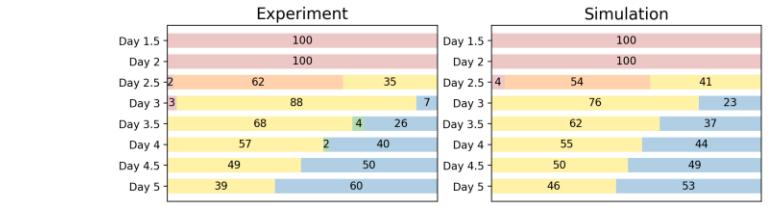

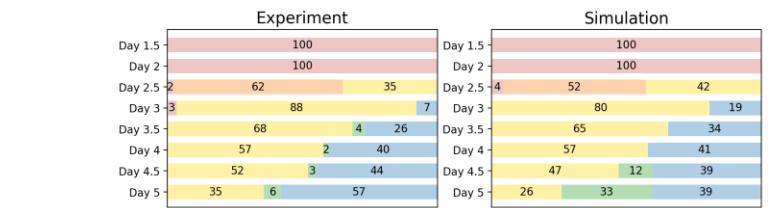

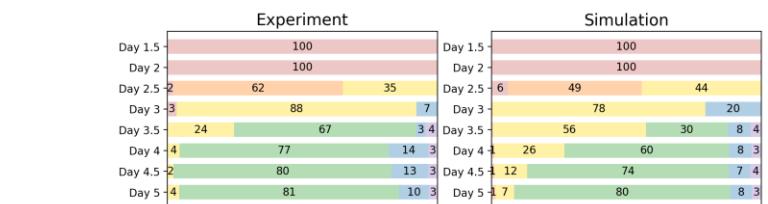

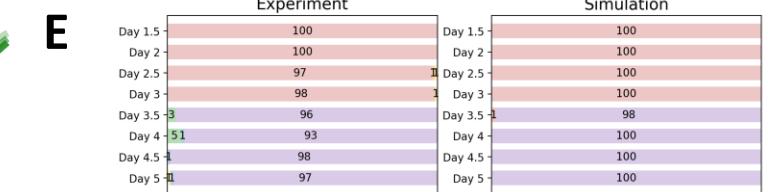

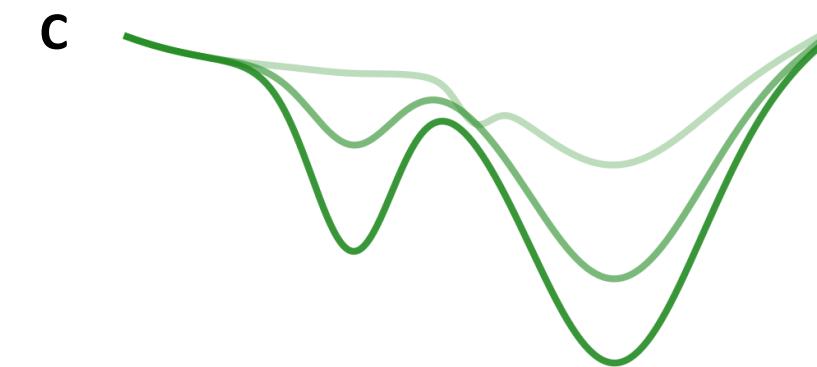

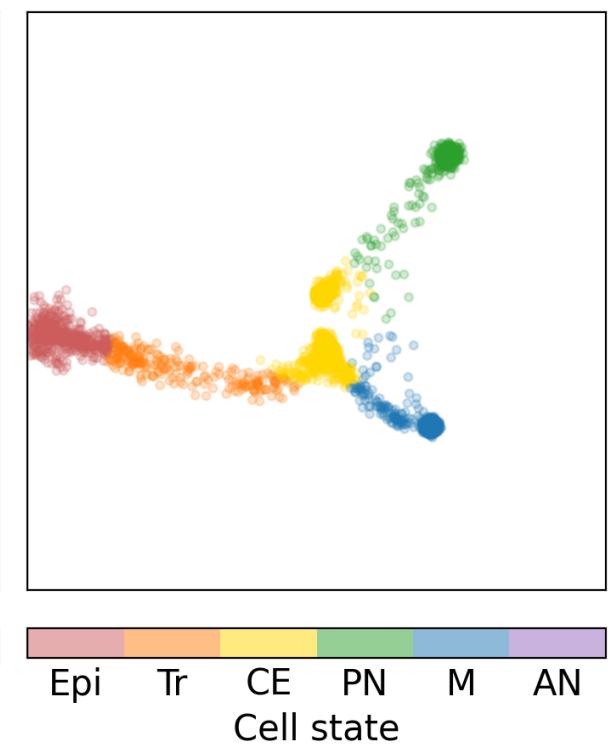

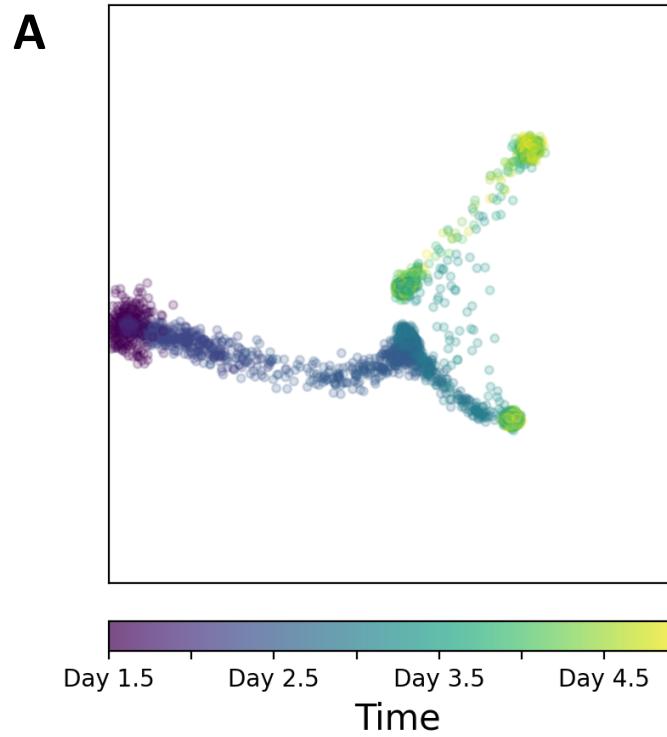

Finally, the *Transient/mixed state* category contains landscapes where PN or M acts as a transient state, or where two modules are merged into one attractor. These have assignment-based spatial structure rather than attractor-based.

Heteroclinic flip landscapes
